WARNINGS

1. X Radiation

This chassis has been designed for minimal x-radiation hazard. However, to avoid possible exposure to soft x-radiation it is **IMPERATIVE** that the EHT circuitry **IS NOT** modified.

2. HIGH VOLTAGE

This monitor contains HIGH VOLTAGES derived from power supplies capable of delivering LETHAL quantities of energy. To avoid DANGER TO LIFE, do not attempt to service the chassis until all precautions necessary for working on HIGH VOLTAGE equipment have been observed. In order to prevent damage to solid state devices, do not arc pix tube anode lead to chassis or earth ground.

3. CRT Handling

The picture tube encloses a high vacuum and due to the large surface area is subject to extreme force. Care must be taken not to bump or scratch the picture tube as this may cause the tube to implode resulting in personal injury and property damage. Shatter-proof goggles must always be worn by individuals while handling the CRT or installing it in the monitor. Do not handle the CRT by the neck.

4. To prevent fire or shock hazard DO NOT EXPOSE THIS MONITOR TO RAIN OR MOISTURE.

5. FILE SUPPLEMENTARY MODEL DATA WITH THIS G05 MANUAL.

PRODUCT SAFETY SERVICING GUIDELINES

CAUTION

No modification of any circuit should be attempted. Service work should be performed only after you are thoroughly familiar with all of the following safety checks and servicing guidelines. To do otherwise increases the risk of potential hazards and injury to the user.

SAFETY CHECKS

Subject: Fire and Shock Hazard

1. Do not install, remove, or handle the picture tube in any manner unless shatter-proof goggles are worn. People not so equipped should be kept away while picture tubes are handled. Keep the picture tube away from the body while handling.
2. When service is required, observe the original lead dress. Extra precaution should be given to assure correct lead dress in the high voltage circuitry area. Where a short circuit has occurred, replace those components that indicate evidence of overheating. Always use the manufacturer's specified replacement component. See parts list in the back of this manual.
3. Periodically check the high voltage for proper value (12. KV at O beam current) using a meter of known accuracy and calibration.
4. Check for frayed insulation on wires.
5. If service is performed on the EHT Module, the EHT overvoltage Limit circuit MUST BE VERIFIED AS OPERATING AT 18.5 KV MAXIMUM.

OPERATING INSTRUCTIONS

1. Apply a suitable power and signal source to the monitor regulator PCB by means of P100.
2. **Brightness and Contrast**
These controls are preset at the factory, but may be adjusted to suit program material. They are located on the right hand edge of the deflection amplifier PCB. R517 is the brightness control and R514 is the contrast control. Both are finger adjustment controls.

Caution must be exercised when adjusting the brightness control. This control has more than 100% brightness range on most tubes. This control should be maintained below the point where a center spot appears on the CRT under a no input signal condition. Adjusting the control above this point may result in a phosphor burn.

4. **Spot Killer Indicator**
A spot killer circuit is used to blank the CRT under a no signal condition. When the spot killer is active, the CRT will be extinguished and LED D504 will light indicating spot killer operation.
5. **Power Down**
The signals that drive the X-Y monitor must be removed before the monitor is powered down. This sequence must be followed or a phosphor burn may result. This damage is permanent and cannot be repaired.

PERFORMANCE DATA

INPUT AND ADJUSTMENT DATA

1. Supply Voltage

A.C. power must be applied to the monitor through plug P100 from the isolated secondary winding of a power transformer, capable of supplying the following voltages at line frequencies from 47 to 63 Hz.

Model G05-802 (19")

Model G05-805 (15")

Main Winding: 30-0-30 VAC RMS + 10-15% at 2 amps maximum.

Filament Winding: 6.3 VAC \pm 10% at .45 amps.

Pin Assignment of P100:

Pin No.	Description
1	Z input .5V blanking 1.0V black level 4.0 V full on 220 ohm impedance
2	Y input \pm 7.5V 1K impedance
3	X input \pm 10V 1K impedance
4	Power GND (CT.)
5	Y signal GND
6	X signal GND
7	30 VAC RMS
8	Z signal GND
9	6.3V AC heater input
10	30 VAC RMS
11	Power GND (CT.)
12	Heater GND

2. High Voltage (EHT)

12.0 KV at zero beam current.

3. Customer Controls

- a) Brightness Control: Located on deflection amp printed circuit board. Control is finger adjustable.
- b) Contrast Control: Located on deflection amp printed circuit board. Control is finger adjustable.

4. Service Controls — These are factory preset and should only be adjusted by trained personnel.

- a) High Voltage Adjust: Located in EHT supply module. Hole in screen cover provides access to this control.
Caution — Use insulated tool to adjust.
- b) Linearity Controls: R700 and R702 are linearity controls for "X" channel. R600 and R602 are linearity controls for "Y" channel. These controls are located on the deflection amplifier printed circuit board.
- c) Focus Control: Located in EHT supply module. Hole in supply heat sink/wrap provides access to this control.

MAXIMUM HIGH VOLTAGE TEST

*If the EHT module requires servicing this test must be performed.

Remove signals to X, Y and Z channels. This can be done by unplugging Pins No. 1, 3, 5 in harness coming from P100. Insert a 20 KV FSD EHT meter on the CR7 anode.

Power up the monitor and adjust the line voltage until the AC input to the bridge rectifier DB100 is 66 VAC CT instead of the nominal 60 volts. Turn brightness control to minimum.

While observing the EHT meter, short the regulator transistor Q900 Collector to Emitter with a screw driver and note the maximum high voltage obtained. This voltage must be less than 18.5 KV. A voltage reading over this value indicates an out of tolerance high voltage module and this condition must be corrected before the module is put back into active service.

CIRCUIT DESCRIPTION

HV MODULE

The high voltage module has been designed to operate over an input supply voltage range of 31 to 42 volts and an ambient temperature range of 0 to 55° C. The module produces nominal voltages of:

- 12 KV at 200 ua
- 400 volts G2 voltage
- 0 to 400 volts focus
- 90 volts for Z amplifier

The circuit can be broken down into two basic sub-systems, the regulator and high voltage generator.

REGULATOR

This is a series regulator with Q900 being the control element. Since any change in high voltage will be reflected back to the 90 volt line, these variations are sensed, amplified and used to control the series pass transistor which then supplies more or less voltage as may be needed to maintain a relatively stable CRT anode voltage. The primary function of R900 is to limit the high voltage generated under a regulator failure condition. It also serves to limit dissipation in Q900. The high voltage supply is fused by F102, a 1A slow blow fuse, located on the deflection PCB. The high voltage supply is isolated from the main ripple component of the primary filters by D100 and C900.

HIGH VOLTAGE GENERATOR

The high voltage generator is a free running Hartley oscillator that operates at approximately 30 KHz. The oscillator transistor is Q903. The voltage made available from the pass transistor is stepped up by means of T900 and rectified to produce 12 KV anode voltage. One other tapped winding produces operating voltages for G2 and focus electrodes of the CRT, and Z amplifier. All of the secondary diodes are of the fast recovery type to operate efficiently at the 30 KHz oscillator frequency.

DEFLECTION PCB

Z AMPLIFIER

Transistor Q504 forms a common emitter amplifier. A TTL compatible brightness signal is applied by means of P100-5. An amplified and inverted replica is present at the collector and this is applied to the CRT cathode. AC gain (contrast) is controlled by R514 and fixed resistor R513. Transistor Q503 is normally biased on very hard by means of R511, R512 and may be treated as a low value resistor that plays no significant part in active amplification of the signal.

Brightness is controlled by varying the DC potential at G1 of the CRT, by means of R517. Diode D506 and C504 isolate and hold the cathode voltage high during power down to prevent phosphor burn. At the same time as the 90 volt line is decaying, the bias for Q503 is lowered, turning the transistor off and further retarding discharge of C504.

SPOT KILLER

The deflection signal is sampled for rate of change and amplitude on both channels, by means of R500, R501, C500, C501 and then rectified to form a negative holding voltage on C502, C503. This negative voltage holds Q500 and Q501 off. There is no current flow through Q502 and LED D504 is not lit. When the sampled signal falls below minimum requirement then the positive voltage applied by R506, R507 turns on Q500, Q501. This causes Q502 to conduct, allowing the LED to illuminate and apply sufficient positive voltage to the emitter of Q503 to cut the transistor off, thereby blanking the display.

POWER SUPPLY

A 60 V CT voltage is applied by means of P100-7, 8, 9, 10. These lines are fused by F100, F101 and applied to bridge rectifier DB100. The resulting DC is roughly filtered by means of C100 and C101 and then applied to the circuitry. R100 and R101 serve to limit inrush current to the filters and offer some protection to DB100 in case of a fault condition. Typical operating voltages are ± 34 VDC.

The DC voltage to the high voltage supply is taken off before the current limiting resistors and is separately fused by F102. The EHT supply voltage is isolated from the main filter ripple component by D100. With the EHT supply functional, a normal operating voltage at P500-10 would be + 40 V.

DEFLECTION AMPLIFIER

Both X and Y channels are identical. Because of this we will investigate only Y channel operation. There are minor resistor value changes in R704, R604 to accommodate the 19" and 15" CRTs of the G05-802 and G05-805 models. The amplifier is a direct coupled voltage to current converter. The small signal response of the amplifier is approximately 1 MHz. Large signal slew rate for full deflection is approximately 150 usec.

The input signal is pre-distorted by the components located within the input bridge comprised of D600, D601, D602, D603, to compensate for inherent CRT non linearity in deflection. Controls R600 and R602 are used to set size and linearity. The gain corrected signal is applied to the base of the input differential amplifier whose constant current source is formed by Q604, Q606, D607 and R611. The reference diodes are also shared by a second constant current source Q607.

The amplified signal is applied to a cascode stage formed by Q605, Q606 and then applied to the bases of output transistors Q608, Q609. These transistors are operated class B in an emitter follower configuration. Current is coupled through F600 to the yoke and then to ground through the sense resistor R620. Very heavy feedback is applied from R620 to the base of Q603, to correct for any non linearities in the amplifier. A considerable amount of power supply ripple can be tolerated because of the push pull arrangement of output transistors, and the cancelling effect of such a stage on any common ripple component. R621 serves as a critical yoke damping resistor.

SERVICE INFORMATION

DEFLECTION AMPLIFIER

This board is held in place by 2 mounting screws and 2 retaining clips. There is sufficient slack in the harness so that service may be performed with the set operating and this board removed from its mounting position. All of the plugs are keyed so improper termination would be difficult.

The linearity controls R700, R702 X channel, and R600, R602 Y channel are factory sealed and do not normally require adjustment. If adjustment is necessary the seals must be broken and a generator capable of displaying a diagonal crosshatch pattern on the monitor must be used. Adjustment, while not impossible, would be difficult on a conventional crosshatch pattern. The nominal input of ± 10 and ± 7.5 volts must be used. Both linearity controls interact. They must be adjusted for best overall linearity with a displayed pattern size of $11\frac{1}{4} \times 15$ inches for G05-802 and $8\frac{7}{8} \times 11\frac{1}{4}$ inches for G05-805. Before adjustment is undertaken, EHT should be verified as being 12 KV 0 beam. Should the sense resistors R720, R620 need replacement, they must be replaced only with resistors of the same value or monitor performance will be degraded.

Both output channels are fused. The fuses must be replaced with similar fuses for continued protection.

Caution: Removal of any plug on the deflection board other than input plug P100 on an operating monitor could result in phosphor burn.

EHT MODULE

The CRT anode voltage is adjustable by means of R905. This control is accessible through the top perforated shield of the module. A small flat blade screwdriver of non metallic composition should be used for this adjustment. The EHT is adjustable from approximately 10 KV to 14 KV at 0 beam current. Nominal EHT is 12.0 KV at 0 beam current.

Focusing may be set by means of R909. This control is accessible through the side shield of the module. It is a flat blade screwdriver adjustment. The focus voltage is adjustable over the range of 0 to 400 volts. Focus should be set for best overall definition.

The fuse for the EHT supply is located on the Deflection PCB. This fuse must be replaced only with a slow blow device of equivalent rating.

When replacing the EHT module, make certain that the CRT anode is safely discharged to ground before removing the anode cap. Make certain the ground wire coming from the rear of the module is re-attached before operating EHT module in the monitor. This ground wire prevents damage to the oscillator transistor in the event of internal arcing in the CRT.

Typical input current from the 40 V line for a normally operating unloaded EHT module is .3 amps. Input current will increase with loading and higher than 12 KV EHT.

Under a load of 200 ua the EHT should not change by more than 300 volts from 12 KV.

A suitable load can be made from 6, 10 M ohm 1W resistors in series. Caution must be used when doing this check.

The 90V line should be capable of supplying 25 ma output current with good regulation. A suitable load would be a 3k9 ohm 2W resistor momentarily held on to the 90V terminal. The output voltage should not drop by more than 5 volts.

The focus and G2 voltages are capable of only very low current drain; they are potential voltages only.

CRT REPLACEMENT

Caution: CRT anode should be discharged to aquadag ground strap before attempting replacement. All precautions regarding CRT handling should be observed.

Remove CRT socket, yoke and anode lead. The CRT may then be removed by loosening the four front panel mounting screws. It will be necessary to verify centering, geometry and linearity. Adjustment may be necessary.

CENTERING ADJUSTMENT

In a semi-dark area with no signal input, brightness control at minimum (maximum CCW rotation), and the yoke unplugged, apply power to the set and after thirty seconds warm up time carefully advance the brightness control until a just visible spot appears on the CRT. Adjust this spot to the geometric center of the CRT by means of the centering rings. Reduce the brightness control to minimum and switch off the set. Plug in the yoke.

GEOMETRY ADJUSTMENT

Before adjusting the geometry verify that the EHT is 12 KV. Set the signal generator to display a rectangle of $10\frac{1}{2}$ " x 14" on G05-802 and $10\frac{1}{2}$ " x $7\frac{7}{8}$ " on G05-805. Adjust the brightness control for comfortable viewing of the display, keeping below the point where a no signal center spot appears on the CRT. Correct any yoke tilt and tighten the yoke clamp. Check that maximum geometry distortion falls within the guidelines as described in the following diagram. Geometry distortion is corrected by proper positioning of magnets on the yoke housing.
